(Received 03 March 2016; published online 21 June 2016)

The electronic property and the magnetism of AlGaMnP₂ compound by 3.125 %, 6.25 %, and 9.375 % Mn concentrations were investigated using the first-principles calculations. The Mn-doped AlGaP₂ chalcopyrite with or without defect of Al, Ga, or P atom yields a strong half-metallic ground state. The ferromagnetic state is the most energetically favorable one. The spin-polarization of Mn dopant is stable with a magnetic moment close to 4μₚ due to intra-atomic exchange coupling. The states of host Al, Ga, or P atoms at the Fermi level are mainly a P-3p character, which mediates a strong interaction between the Mn-3d and P-3p states. The ferromagnetic state with high magnetic moment is originated from the hybridized P(3p)-Mn(3d)-P(3p) interaction formed through the p-d coupling without the defects. It is noted that the ferromagnetism arises from two distinguishing characteristics by polarons and by holes-mediated exchange-coupling.

1. INTRODUCTION

Diluted magnetic semiconductors (DMSs) have paid much attention because the s and p electrons of the nonmagnetic materials and the spin from the magnetic dopant can be employed in spintronic devices [1-5]. The spin-polarization in the semiconductor has tended to disappear quickly by spin-flip scattering, when the charges of ferromagnetic (FM) matters are implanted as spin injectors. Until now, the opportunities of DMS’s devices have been limited because the low solubility of magnetic ions in non-magnetic matters. Thus it is a great worth to handle the FM semiconductor because the difficulty in the spin-injection to make DMSs at room temperature.

It has been reported that the Mn-doped ZnSnAs₂ [6] and ZnGeP₂ [7] shows the ferromagnetism at 320 and 312 K, respectively. Newly synthesized a MnGeP₂ ternary compound has been reported as a semiconductor, whose crystal structure is chalcopyrite [8]. It has been reported that a MnGeP₂ exhibits ferromagnetism with Tₑ = 320 K and a magnetic moment per Mn at 5 K of 2.58 μₑ, and an indirect energy gap of 0.24 eV. In the working for Ion implantation of Cr or Mn at concentrations of 1-5 at. % in AlGa₁₋ₓP (x = 0.24, 0.38), the ferromagnetism above 100 K for Cr and 300 K for Mn in AlGaP has been reported [9, 10]. The Mn rather than Cr dopant appears to be a more promising a high temperature ferromagnetism of AlGaP.

AlP is unstable in air and oxidizers rapidly. However, ternary AlGaP material is used in device structure, we see it can enhance the Curie temperature above while maintaining material stability. Other recent experiments for Mn-doped GaP show the FM ordering above 300 K [11-13]. The Curie temperature is largely affected by a type in the matter and the density of carrier. The p-type shows much higher than that of undoped or n-type matters. Accordingly, it can find that the Curie temperature increases for the concentration of Mn dopant. In this paper, we had studied by using ab-initio calculations for the electronic properties and magnetic characteristics of (Al,Mn)-codoped to fabricate GaP-based DMS. In the system of AlGaP; Mn, we had observed FM ordering with high magnetic moment (3.7-4.2μₑ/Mn). We had predicted that AlGaP ternary compound has a character of chalcopyrite semiconductor with a direct band gap.

2. COMPUTATIONAL DETAILS

This work was carried out using a self-consistent full-potential linear muffin-tin orbital (LMTO) method [14] based on spin density functional theory within the generalized gradient approximation (GGA). We used the exchange-correlation functional of Perdew-Burke-Ernzerhof scheme [15]. The radii of muffin-tin (MT) sphere for Mn (or Al, Ga) and P were chosen to be 2.4 and 1.9 a.u., respectively. The LMTO basis set and charge density in each MT sphere were expanded with real spherical harmonics up to l = 6, where l is the angular momentum defined inside each MT sphere. The LMTO basis functions for Mn and Ga atoms within the valence-energy were chosen as 4s and 3d, and 4s, 4p, and 3d, respectively. The electron wave function was expanded in plane wave with a cut-off energy of 159.12 eV, 232.56 eV, and 340.0 eV for the Mn-4s (or Al-3s), Mn-4p (or Al-3p), and Mn-3d, respectively. The relativistic effect for the valence electrons was taken into account by the scalar-relativistic approximation. The MT approximation was employed in order to describe the atomic potential, the effects of spin-orbital coupling of valence electrons were not included. The linear tetrahedron method [14] over a gamma-centered 4 × 4 × 4 mesh in the Brillouin zone was used. The 4 × 4 × 4 mesh is corresponding to 64 k-points. Using these k-points insured that the total energies and the

¹ kmsong@kkku.ac.kr
magnetic moments were converged on a better 10 meV/cell and 0.01 μB/atom, respectively. Broyden and linear mixing strategies for the input and the output charge-density were used to accelerate convergence of spin and charge densities [14]. The electronic structure and magnetic properties on the (Al,Mn)-codoped GaP semiconductor had been performed. We had investigated for three Mn concentrations of 3.125 %, 6.25 %, and 9.375 %.

3. RESULTS AND DISCUSSION

A. Structural properties

The atomic structure of Al-doped GaP was considered as the tetrahedrally-coordinated zinc-blende materials. The chalcopyrite is a class of semiconductor confirmed as a promising material to fabricate nonlinear optical devices. The III-III-V2 alloys crystallize in a form of AlGaP2 chalcopyrite structure. The tetrahedral chalcopyrite structure was displayed in the Fig. 1. First, we performed the atomic geometry and positions of the structures are fully relaxed until the force between atoms is less than 1.0 mRy/Bohr. For the AlP, GaP, and pure AlGaP2 systems, we considered the atomic relaxations for the positions of the structures. However, the distortions of near host atoms by substituting Mn dopant in the AlGaP2 bulk were neglected. For the AlP, GaP, and AlGaP2 systems, the obtained lattice parameters from first-principles calculations are a = 5.726 Å and c = 11.452 Å for GaP; a = 5.648 Å and c = 11.296 Å for AlP. For AlGaP2, they are a = 5.685 Å, c = 11.222 Å, and c/a = 1.974. For the GaP and AlP systems, the total-energy minimization of the supercell with keeping a c/a = 2.0 was performed. For the AlGaP2 system, we considered the structural relaxation for each of a and c-axis. The calculated parameters for GaP and AlP can be compared with that of the zinc-blende structure. The experimental values are a = 5.451 Å and 5.450 Å for GaP [16, 17] and AlP [16], respectively. These chalcopyrite structures for GaP, AlGaP2, and AlP exhibit the semiconducting character with energy gaps of 1.679 eV, 1.241 eV, and 0.276 eV, respectively. For the ternary alloys, the variation of the lattice parameter for each crystalline and the energy gap with compositions were shown in Fig. 2. It can be seen a downward bowing of the lattice parameter as increases Al concentration in the AlGa1-xP2 system (x = 0.0, 0.25, 0.75, and 1.0). While for the calculated band-gap, it increases from 0.276 eV to 1.679 eV. The calculated result of bandgap is smaller than that of the experiment [18]. It is general trend that the results by using the GGA are less than half of that of the experiment. Maybe it can be

obtained the result that the calculated value in the LDA + U [19] is slightly larger than that in the GGA.

The (Al, Mn)GaP2 and Al(Ga, Mn)P2 corresponds to the case of Ga-rich and Al-rich systems, respectively. We observed that the Al(Ga, Mn)P2 is the lowest energetically favorable system with or without a vacancy of Al, Ga, or P atom. The Al(Ga, Mn)P2 is more energetically favorable than the (Al, Mn)GaP2. For the defect systems, it can be seen in the Table 1. In the case of without a vacancy, the difference in the substitution energies between the (Al, Mn)GaP2 and Al(Ga, Mn)P2 is very small. Their energy are −346.5 meV/Mn and −282.2 meV/Mn for Al(Ga, Mn)P2 and (Al, Mn)GaP2, respectively. In the case of with a Ga vacancy, the migration energy of Mn into a defect site is the lowest by −0.338 eV as compared to that of other system as seen in Table 1. The migration energy of Mn atom into the interstitial or the defect sites was defined as

![Fig. 1](image1.png)

![Fig. 2](image2.png)  
Fig. 2 – Optimal lattice constants, a, and calculated band-gap for AlGa1-xP2 alloys. Total-energy differences as a function of lattice parameter for the GaP and AlP structures are shown in the inset.
$E_{\text{intol}} \text{Mn} = E(\text{AlGaP}_{2-3}\text{V(Al/Ga/P);Mn}) - E(\text{AlGaP}_{2}) - n_{1}\mu_{\text{Al}} + n_{2}\mu_{\text{Ga}} + n_{3}\mu_{\text{P}} + n_{4}\mu_{p}$

Here, $E(\text{AlGaP}_{2-3}\text{V(Al/Ga/P);Mn})$ and $E(\text{AlGaP}_{2})$ are the total energies of Mn-doped AlGaP$_2$ with a vacancy of Al, Ga, or P and the pure AlGaP$_2$ systems for the supercell of the same size, respectively. The integer $n_1$, $n_2$, $n_3$, and $n_4$ are the number of doped Mn atoms on the Al, Ga, and P sites. The $\mu_{\text{Al}}$, $\mu_{\text{Ga}}$, $\mu_{\text{P}}$, and $\mu_{p}$ are the atomic chemical potentials of Mn, Al, Ga, and P. The chemical potentials will be depended on the experimental conditions. The relationship of $\mu_{\text{Al}} + \mu_{\text{Ga}} + 2\mu_{p} = \mu_{\text{AlGaP}}$ is formulated in thermal equilibrium of AlGaP$_2$. The $\mu_{\text{Mn}}$ will be determined by the equilibrium of bulk MnP, which has the FM phase with a Neel’s temperature of 291 K [20]. $\mu_{\text{Al}} = E(\text{AlP}) - E(\text{P})$ and $\mu_{\text{Ga}} = E(\text{GaP}) - E(\text{P})$. For Al-rich system, $\mu_{\text{Mn}} = E(\text{MnP}) - E(\text{AlP}) + E(\text{Al})$ and $\mu_{p} = E(\text{AlP}) - E(\text{Al})$; and for Ga-rich system, $\mu_{\text{Mn}} = E(\text{MnP}) - E(\text{GaP}) + E(\text{Ga})$ and $\mu_{p} = E(\text{GaP}) - E(\text{Ga})$.

**Fig. 3** – DOS for Al, Ga, P, and Mn sites of 6.25 % Mn-doped AlGaP$_2$ within FM state. The dotted line at zero presents the $E_F$. Energy-band along symmetry direction of AlGaP$_2$ is shown in the inset, indicating semiconducting character with direct bandgap.

**B. Electronic properties**

Fig. 3 illustrates the partial density of states (DOS) for Al$_1$–Mn$_y$Ga$_{1-y}$P$_2$ at $y = 0.0625$. We could find the perturbation of valence state by Mn atom in the AlGaP$_2$. The minority-band shifts downward about 0.5 eV in comparison with un-doped AlGaP$_2$. While the majority-band shifts upward by about 0.5 eV. It is formed a localized state just at the Fermi energy ($E_F$). We could find that the majority band on the $E_F$ is mainly composed of Al-3$p$ and Ga-4$p$, and P-3$p$ states. The majority Mn-3$d$ state is occupied at the low-energy region below the $E_F$, while the minority Mn-3$d$ state contributes to the high energy region above the $E_F$. These majority $p$ states make a result of strong hybridization between the P-3$p$ (or Al-3$p$, or Ga-4$p$) and Mn-3$d$ ($d_{z^2}$, $d_{x^2-y^2}$) bands, or Mn-3$d$ ($d_{x^2-y^2}$) bands. $J_H$ is corresponds to the bandwidth between Mn-3$d$ majority and minority states (see Fig. 3). The P-3$s$ state is localized below $E_F - 10.5$ eV. The partially filled Mn $e$-band lies on the $E_F$ (majority states), while the $t_2$-band goes down in the valence band by $E_F - 2.5$ eV. The electron overlap indicates that there is the hybridizations between the Mn-3$d$ and 3$p$ (or 4$p$) electrons of P, Al, or Ga atom. Especially, a strong interaction between the Mn-3$d$ and P-3$p$ electrons is induced because an accumulation of carrier between these states just on the $E_F$. Hence the partially filled P-3$p$ band contributes to the ferromagnetism with high magnetic moment. These configurations provide a clue to explicate the characteristics of holes-mediated ferromagnetism in the Mn-doped AlGaP$_2$ DMS. The ferromagnetism is stable by intra-atomic exchange interaction (Hund’s coupling).

The Mn dopant orders ferromagnetically in AlGaP$_2$. The FM state is energetically stable as compared with the non-magnetic or antiferromagnetic (AFM) state. The total-energy difference between the FM and AFM states is $-99.7$ meV in the Mn concentration of 6.25 %. For Al$_1$–Mn$_y$Ga$_{1-y}$P$_2$ for $y = 0.0625$ without a vacancy, the nearest neighboring four surrounding P atoms formed the MnP$_{4}$ tetrahedron are aligned positively with magnetic moments of 0.03$\mu_B$ per P atom. While for the nearest neighboring Al or Ga atoms, it is aligned negatively with magnetic moment of $-0.02\mu_B$ per Al or Ga atom. The substituted Mn atom has a high magnetic moment of 3.84$\mu_B$ per Mn atom. The magnetic property of Mn atom is maintained to the ferromagnetism with a high-spin state as increasing up to the concentration of 9.375 % Mn. The magnetic moment is nearly constant. For the system with the vacancy of 3.125 % Al, Ga, or P, the magnetic moment of the nearest neighboring P atom to the vacancy is aligned negatively, while for the nearest neighboring Al, Ga, or Mn atoms, it is aligned positively. The Mn magnetic moment is 3.7–4.2$\mu_B$ per Mn atom. The Mn-doped AlGaP$_2$ with or without a vacancy is retained a strong half-metallic character. However, it is disappeared the half-metallic property in the case of Mn migration into the interstitial site. These results were listed Fig. 4, Fig. 5, and Table 2.

The origin of ferromagnetism of the half-metallic DMS with the defects can be explained by bound magnetic polaron (BMP) [20]. This is that the exchange
interaction between the localized carriers trapped by vacancy and the spin-polarization of neighboring Mn$^{2+}$ ions forms a BMP. A large BMP through the supercell gives rise to the ferromagnetism. The BMP is stable under a strong localization of carriers. For the half-metallic DMS without the defects, the FM state arises from the holes-mediated characteristics. The states of Ga-3$d$ electrons is very little at the near the $E_F$. It is localized below a –12 eV in the core region. So, the $d$-$d$ interaction between the Ga and Mn atoms is very weak. The substituted system of Al by Mn atom and the system of Mn migration show the half-metallicity by downward shift of Al, Ga, and P minority bands. The Mn-P bond is a covalent due to the hybridizations between the Mn-3$d$ and P-3$p$ electrons. The direct $d$-$d$ interaction between Mn atoms may be small because the variance of magnetic moment for the Mn concentration is nearly constant. Thus the ferromagnetism of Mn dopant maybe imply a direct exchange mechanism by the P site.

4. CONCLUSION

We had studied the magnetism and electronic properties for Mn dopant in the chalcopyrite AlGaP$_2$ semiconductor by using the full-potential LMTO method. The systems of Al$_{x}$Ga$_{1-x}$P$_2$ ($x = 0.0, 0.25, 0.75, and 1.0$) and Mn-doped AlGaP$_2$ with or without the defects by Mn concentration of 3.125, 6.25, and 9.375 had been investigated. The AlGaP$_2$ compound is a p-type semiconductor with a band gap of 1.24 eV. The FM state is the most stable with increasing of Mn-doping concentration. We had observed that these systems with or without the defects exhibit the half-metallic FM state. The FM ordering of Mn dopant and four neighboring P

Atoms are produced by strong p-d hybridization. We had noted that a high magnetic moment of Mn is maintained by the hybridized P(3p)-Mn(3d)-P(3p) interaction in the case of without a vacancy. In conclusion, there are two distinguishing characteristics by polarons in the case of with a vacancy and by holes-mediated exchange coupling in the case of without a vacancy.
