(Received 31 October 2017; published online 29 April 2018)

A mathematical model is developed to determine the force impacts that are formed when the electromagnetic field is transformed into a field of ultrasonic oscillations in the skin layer of an electrically conductive ferromagnetic material of an anisotropic magnetic permeability. The main factors determining the excited acoustic field with allowance for permissible limitations are established. It is shown that the main contribution to the acoustic vibrations energetics is made by the magnetostrictive component of the skin layer material, in which the high-frequency electromagnetic field is transformed into an acoustic field.

1. INTRODUCTION

Magnetic materials are the basic materials of magnetoacoustics, microwave engineering, magneto-optics and spintronics. Nanostructuring of volumetric materials allows controlling their characteristics in a wide range. Nanocrystalline ferromagnetic soft magnetic materials with low coercive force and ultra-high permeability are most frequently used. The effect of magnetoresistance in film multilayer materials makes it possible to create on their basis high-sensitive heads for magnetic disks, which read information in computers. When developing technology for the formation of both bulk nanostructured materials and film multilayer instrumental structures, it is necessary to control their physical properties by non-destructive testing methods. When developing such methods, an urgent task is to create ultrasonic frequency sensors for the study of nanocrystalline ferromagnetic materials.

In [1], in a general form, the problem of electromagnetic excitation of elastic oscillations in the micro-thick layers (films) of ferromagnetic metals with the corresponding boundary conditions was formulated and solved, where a linear approximation of the phenomenological theory of magnetostrictive phenomena was used. It is shown that the mathematical model of the transformation process of electromagnetic energy into acoustic one in the skin layer of metal must take into account the coherence of the elastic and magnetic fields in the volume of the dynamically deformed micro-thick layer of an electrically conductive ferromagnet. At the same time wave-length of an excited elastic wave will be significantly larger than skin-layer thickness, therefore providing almost constant within cross-section stress-deformed state of metal layer. Boundaries are determined at which the increase in the mechanical rigidity of the preliminarily magnetized ferromagnet due to the coupling effect of the elastic forces and the forces of the magnetic interaction between the poles of the domains in the deformed thin layer of the ferromagnet can be ignored.

At the same time in order to create the physical basis for thin material surface layer investigation sensor design, by-layer method included, using, for example, frequency change of active electromagnetic field, it is required to define the force parameters affecting skin-layer area of given size, in turn defining most of important attributes of excited acoustic field.

2. PROBLEM STATEMENT

Let us consider a model of an electromagnetic transducer (Fig. 1), in which the source of alternating magnetic field (position 1) is formed from N turns of wire, which is laid in concentric circles in a flat coil. The height of the coil is b, inner and outer radii of laying turns are R₁ and R₂ correspondingly. The coil 1 is placed in vacuum at the distance of δ over the ferromagnetic metal layer (of 2h thickness) surface 2. Inside the layer 2 a constant magnetic field is created. Magnetic induction vector is completely defined by its axial component \( B_0^z \), which is a constant in circular area \( \rho \leq R_0 \), where \( R_0 > R_2 \).

![Fig. 1 – Model design scheme (1 - alternating magnetic field; 2 - layer of ferromagnetic metal)](image-url)
When alternating electric current $i(t) = I_0 e^{i\omega t}$ flows through the coil turns, axisymmetric alternating magnetic field appears in the skin layer of the metallic ferromagnetic plate with vector $H_\parallel (\rho, z, t)$ which intensity varies in time according to the law $e^{i\omega t}$ with the amplitude value $H_\parallel (\rho, z)$, where $\rho, z$ are the coordinates of the point in the cylindrical coordinate system $(\rho, \varphi, z)$, the plane $z = 0$ which is aligned with the middle plane of the layer. The cumulative effect of alternating and constant magnetic fields generates in a volume and on the surface of the ferromagnetic layer the Lorentz forces and magnetostriction forces, which we will henceforth call the Joule forces.

3. ANALYSIS OF THE FORCE FACTORS THAT ARE FORMED BY THE ELECTROMAGNETIC TRANSDUCER IN THE SKIN LAYER AND IN THE VOLUME OF THE FERROMAGNET

In order to perform a comparative evaluation of the above-mentioned factor forces, we determine the amplitude values of the radial $H_\parallel^r (\rho, z)$ and axial $H_\parallel^a (\rho, z)$ components of the intensity vector of alternating magnetic field in the ferromagnetic plate. Let us consider alternating magnetic field in the region No.1, where $h \leq z < \infty$. The amplitude value of the intensity vector of the field is

$$-A_{\varphi, rz} (\rho, z) + \frac{1}{\rho} A_{\varphi, r} (\rho, z) - \frac{1}{\rho} A_{\varphi, \rho} (\rho, z) - A_{\varphi, \varphi} (\rho, z) = \mu_0 J_0 (\rho) \psi_3 (z),$$

For the vector potential $A_{\varphi} (\rho, z)$ boundary conditions are to be met:

$$\lim_{r \to \infty}[\rho A_{\varphi} (\rho, z); \rho A_{\varphi, r} (\rho, z); \rho A_{\varphi, \rho} (\rho, z)]; \rho A_{\varphi, \varphi} (\rho, z)] = 0, \quad (3)$$

where $r = \sqrt{\rho^2 + z^2}$ is the distance to the source.

To solve the equation (2) let us use the direct Hankel transform.

$$A_{\varphi} (\rho, z) = \frac{\pi}{2} \rho A_{\varphi} (\rho, z) J_1 (\mu \rho) d\rho,$$

where $J_1 (\mu \rho)$ is Bessel function of the first order – the core of the integral transformation; $\gamma$ is a parameter of the integral transformation (real number, determined on a half-open interval $[0, \infty)$). The original image $A_{\varphi} (\rho, z)$ of the unknown function corresponds to the integral image $A_{\varphi} (\gamma, z)$, which is determined from the known value $A_{\varphi} (\gamma, z)$ as a result of the implementation of the inverse integral Hankel transform of the following form

$$A_{\varphi} (\rho, z) = \frac{\pi}{2} \rho A_{\varphi} (\gamma, z) J_1 (\mu \rho) d\rho.$$

Let us influence the (2) equation by the direct transformation (4) receiving

of alternating magnetic field in this region is denoted by the symbol $\tilde{H}^{(1)} (\rho, z)$. In the region No.1 there are external currents with a surface density $j_0 = \tilde{\zeta}_0 \tilde{J}_0$, where $\tilde{\zeta}_0$ – a unit vector of the circular axis of the polar angles, and $\tilde{J}_0$ – a surface density of the external current, herewith

$$J_0 = \frac{I_0 N}{b (R_2 - R_1)} f_1 (\rho) \psi_3 (z), \quad (1)$$

where the regulatory functions $f_1 (\rho)$ and $f_3 (z)$ have the following properties:

$$f_1 (\rho) = \begin{cases} 1 \forall \rho \in [R_1, R_2], \\ 0 \forall \rho \notin [R_1, R_2]. \end{cases}$$

$$f_3 (z) = \begin{cases} 1 \forall z \in [h + \delta, h + \delta + b], \\ 0 \forall z \notin [h + \delta, h + \delta + b]. \end{cases}$$

Let us introduce the vector potential $\tilde{A} (\rho, z)$, where

$$\tilde{A} (\rho, z) = B (\rho, z) = \mu_0 \tilde{H}^{(1)} (\rho, z).$$

In this case, from the first Maxwell equation $rot \tilde{A} = \tilde{j}$ the equation for the vector potential follows, which in extended shape can be written as

$$-A_{\varphi, rz} (\rho, z) + \gamma^2 A_{\varphi} (\rho, z) = \mu_0 R (\rho, z), \quad (6)$$

where $R (\rho, z) = R (\rho, z)$; $R (\rho) = \frac{I_0 N}{b} W (\gamma, R)$;

$$W (\gamma, R) = \frac{\pi}{2(1 - R_1 / R_2)} \left[ \Omega (R_2) - \frac{R_2}{R_2} \Omega (R_1) \right];$$

$$\Omega (R_j) = J_{1} (\mu R_j) \mathbf{H}_1 (\mu R_j) - J_{0} (\mu R_j) \mathbf{H}_1 (\mu R_j),$$

$j = 1, 2$; $\mathbf{H}_1 (\mu R_j) \left( \nu = 0; 1 \right)$ – Struve function of $\nu$ power series.

The solution for the equation (6), which meets the boundary conditions (3), is as follows

$$A_{\varphi} (\rho, z) = [A_0 + A (\gamma) e^{\gamma \rho}] + [B + B (\gamma) e^{-\gamma \rho}], \quad (7)$$

where

$$A_0 = -\mu_0 J_0 N W (\gamma, 1) e^{-\gamma R_1} / (2 \gamma \rho);$$

$$W (\gamma, 1) = \frac{\pi e^{-\gamma R_1}}{2(1 - R_1 / R_2)} \left[ \Omega (R_2) - \frac{R_2}{R_2} \Omega (R_1) \right],$$

$$-\frac{R_2}{R_2} \left(1 - e^{-\gamma R_1}\right). \quad (8)$$

The way the function $W (\gamma, 1)$ changes defines in fact the lower integration limit when performing the reverse Hankel transform in accordance to (5). Analyzing the $W (\gamma, 1)$ function behavior can show that in case of $\gamma R_2 \geq 10$ it has extremely low values for real induc-
tive coil sizes. Therefore integration by (5) on the interval \([\rho R_z, x]\) has no significant impact on reverse Hankel transform. Thus, instead of infinity as upper integration limit in (5) values \(\gamma_{max} \approx 10/R_z\) can be used. When \(R_z = 2.5 \times 10^{-1}\) m we have \(\gamma_{max} = 4000\).

Varied constants \(A(z)\) and \(B(z)\) are defined traditionally

\[
A(z) = -\frac{\mu_0 J_N}{2\gamma} W(y, \gamma) e^{\gamma d} dx ,
\]

\[
B(z) = \frac{\mu_0 J_N}{2\gamma^2} W(y, \gamma) e^{\gamma d} dx .
\]

where \(R(y, x) = R(y, z).\) Symbol \(B\) in (7) marks the constant to be defined. Obviously, when \(z \leq h + \delta\) the varied constants \(A(z) = B(z) = 0.\)

As \(H(\rho, z) = \text{rot} \left[ \vec{A}(\rho, z) \right]/\mu_0,\) then the amplitudes of the components of the intensity vector of alternating magnetic field in the half-space \(z \geq h\) are determined as follows:

\[
H_{\rho}(\rho, z) = -\frac{1}{\mu_0} A_{\rho\rho}(\rho, z),
\]

\[
H_{z}(\rho, z) = \frac{1}{\mu_0} \left( A_{\rho\rho}(\rho, z) + A_{\rho\rho}(\rho, z) \right) . \tag{9}
\]

Let us determine the integral images of the components of the intensity vector of alternating magnetic field according to Hankel with the following expressions

\[
H_{\rho}(\rho, z) = \frac{\rho H(\rho, z) J_1(y \rho)}{0}, \tag{10}
\]

\[
H_{z}(\rho, z) = \frac{\rho H(\rho, z) J_0(y \rho)}{0}. \tag{11}
\]

Influencing on (9) by the integral transformations (10) and (11), we obtain

\[
H_{\rho}(\rho, z) = \frac{1}{\rho} \int_{0}^{\rho} A_{\rho\rho}(\rho, z) J_1(y \rho) d\rho ,
\]

\[
H_{z}(\rho, z) = \int_{0}^{\rho} \left( A_{\rho\rho}(\rho, z) + A_{\rho\rho}(\rho, z) \right) J_0(y \rho) d\rho . \tag{12}
\]

It follows from the computational formulas (12) and (13) and from the definitions of the variable constants \(A(z)\) and \(B(z)\) that at \(z < h + \delta\) the expressions for calculating integral images \(H_{\rho}(\rho, z)\) and \(H_{z}(\rho, z)\) take the following form

\[
H_{\rho}(\rho, z) = -\frac{\rho}{\mu_0} \left( A_{\rho\rho}(\rho, z) - B e^{\gamma \rho} \right),
\]

\[
H_{z}(\rho, z) = \frac{\rho}{\mu_0} \left( A_{\rho\rho}(\rho, z) + B e^{\gamma \rho} \right). \tag{14}
\]

Let us determine the expressions for calculating the amplitude values \(H_{\rho}(\rho, z)\) of the components of the intensity vector of alternating magnetic field in the volume of a magnetized ferromagnet.

The Maxwell equations in the volume of a conducting ferromagnet are written in the following form

\[
\text{rot} \ \vec{H}'(\rho, z) = \vec{J}'(\rho, z),
\]

\[
\text{rot} \ \vec{E}'(\rho, z) = -i \omega \vec{B}'(\rho, z), \tag{15}
\]

where \(\vec{J}'(\rho, z) = \vec{E}'(\rho, z)\) is an amplitude value of the vector density of the eddy current conductivity;

\[
- \left( H_{z,xx}(\rho, z) + H_{z,xy}(\rho, z) + i \omega \mu_0 H_{x}(\rho, z) \right) = 0, \tag{17}
\]

\[
\frac{1}{\rho} \left[ H_{\rho,xx}(\rho, z) - H_{\rho,xy}(\rho, z) \right] + H_{\rho,xy}(\rho, z) - H_{z,yy}(\rho, z) + i \omega \mu_0 H_{z}(\rho, z) = 0. \tag{18}
\]

Let us define the integral images \(H_{\rho}(\rho, z)\) and \(H_{z}(\rho, z)\) by the identical expressions (10) and (11) of the relations, that is,

\[
H_{\rho}(\rho, z) = \frac{1}{\rho} \int_{0}^{\rho} H_{\rho}(\rho, z) J_1(y \rho) d\rho , \tag{19}
\]
\[ H_x^*(y, z) = \frac{\gamma}{\rho} \beta J_0(\gamma \rho) d\rho. \]  

(20)

Applying the integral transformation (19) to the equation (17), and the equation (18) to the transformation (20) we obtain a system of ordinary differential equations of the following form

\[ -H_{\rho,zz}^*(y, z) - \gamma H_{z,z}^*(y, z) + i \omega \mu_0 H_{\rho}^*(y, z) = 0, \]

(21)

\[ \gamma H_{\rho,zz}^*(y, z) + \gamma^2 H_{\rho}^*(y, z) + i \omega \mu_0 H_{z}^*(y, z) = 0. \]

(22)

From the equation (22) it follows that

\[ H_{\rho}^*(y, z) = -\frac{\gamma}{\rho^2 + i \omega \mu_0 \beta} H_{\rho,zz}^*(y, z). \]

(23)

Substituting equation (23) into equation (21), we obtain

\[ H_{\rho,zz}^*(y, z) - \zeta^2 H_{\rho}^*(y, z) = 0, \]

(24)

where \( \zeta^2 = \mu_0^4 \beta^2 + i \omega \mu_0 \beta \) is a square of the complex wave number.

The solution for the equation (24) would be

\[ H_{\rho}^*(y, z) = C e^{i \theta} + D e^{-i \theta}, \]

(25)

where \( C \) and \( D \) are the constants to be determined.

Substituting equation (25) into the definition (23), we obtain a formula for calculating the integral image of the axial component of the intensity vector of alternating magnetic field in the volume of a ferromagnetic plate

\[ \frac{1}{\rho} \left[ H_{\rho}^{(2)}(y, z) - H_{z,\rho}^{(2)}(y, z) \right] + H_{\rho,zz}^{(2)}(y, z) - k_0^2 H_{\rho}^{(2)}(y, z) = 0. \]

(29)

As before, let us define the integral images of the vector components \( \vec{H}^{(2)}(\rho, z) \) by the following Hankel transforms

\[ H_{\rho}^{(2)}(y, z) = \frac{\gamma}{\rho} \beta J_0(\gamma \rho) d\rho, \]

(30)

\[ H_{z}^{(2)}(y, z) = \frac{\gamma}{\rho} \beta J_0(\gamma \rho) d\rho. \]

(31)

Applying the integral transformation (30) to the equation (28), and the transformation (31) to the equation (29), we obtain the following system of ordinary differential equations

\[ -H_{\rho,zz}^{(2)}(y, z) - \gamma H_{z,zz}^{(2)}(y, z) - k_0^2 H_{\rho}^{(2)}(y, z) = 0, \]

(32)

\[ \gamma^2 - k_0^2 H_{z}^{(2)}(y, z) + \gamma H_{z,\rho}^{(2)}(y, z) = 0. \]

(33)

From the equation (33) it follows that

\[ H_{z}^{(2)}(y, z) = -\gamma^2 \frac{\gamma}{\rho^2 - k_0^2} H_{z,\rho}^{(2)}(y, z). \]

(34)

Substituting expression (34) into the equation (32), we obtain an equation for determining the integral image \( H_{\rho}^{(2)}(y, z) \):

\[ \text{rot rot } \vec{H}^{(2)}(\rho, z) - k_0^2 \vec{H}^{(2)}(\rho, z) = 0, \]

(27)

where \( \vec{H}^{(2)}(\rho, z) \) is an amplitude value of time-varying intensity vector of the magnetic field; \( k_0^2 = \omega^2 \mu_0 \chi_0 \); \( \chi_0 = 8.85 \cdot 10^{-12} F/m \) and \( \chi_0 = 8.85 \cdot 10^{-12} F/m \) are magnetic and dielectric constants.

The solution for the vector equation (27) then follow two scalar equations

\[ -H_{\rho,zz}^{(2)}(\rho, z) + H_{z,zz}^{(2)}(\rho, z) - k_0^2 H_{\rho}^{(2)}(\rho, z) = 0, \]

(28)

\[ H_{\rho,zz}^{(2)}(\rho, z) - \left( \gamma^2 - k_0^2 \right) H_{\rho}^{(2)}(y, z) = 0, \]

(35)

The main contribution to the numerical values of the inverse Hankel transform is made by fragments of the integrand at the values \( \gamma \in (500, 1500) \). The latter allows us to state that at frequencies of hundreds of kilohertz – units of megahertz a strong inequality is always realized \( \gamma^2 \gg k_0^2 \). Then the solution for the equation (35) in the area \( \pm \infty < z \leq -h \) is as follows:

\[ H_{\rho}^{(2)}(y, z) = M e^{\gamma z}, \]

(36)

where \( M \) is a constant. Applying (36) to the definition (34) considering that \( \gamma^2 \gg k_0^2 \) we receive

\[ H_{\rho}^{(2)}(y, z) = -M e^{\gamma z}. \]

(37)

The constants \( B, C, D \) and \( M \) from boundary conditions on surfaces \( z = \pm h \)

\[ H_{\rho}^{(2)}(y, h) - H_{\rho}^{(2)}(y, -h) = 0, \]

\[ \mu_0 H_{z}^{(2)}(y, h) - \mu_0 H_{z}^{(2)}(y, -h) = 0, \]

\[ H_{\rho}^{(2)}(y, h) - H_{\rho}^{(2)}(y, -h) = 0, \]
\[
\mu_0^2 H^s_z(y, -h) - \mu_0 H^{(2)}_z(y, -h) = 0. \quad (38)
\]

The system of equations (38) is solved for constants to be defined in the only way.

\[
C = -2\gamma A_0 e^{\mu h} \frac{\beta_1 e^{\mu h}}{\mu_0 \rho_0^2 e^{2\mu h} - \beta_1^2 e^{-2\mu h}},
\]

\[
D = 2\gamma A_0 e^{\mu h} \frac{\beta_2 e^{\mu h}}{\mu_0 \rho_0^2 e^{2\mu h} - \beta_2^2 e^{-2\mu h}},
\]

(39)

where \( \beta_1 = 1 + \mu_1 \gamma / (\mu_0 \xi) \); \( \beta_2 = 1 - \mu_1 \gamma / (\mu_0 \xi) \).

Let us consider the case in which \( h \gg R_2 \). In this case, the ferromagnetic layer can be considered as a half-space (Fig. 2). Between the axial coordinates \( z' \) (Fig. 2) and \( z \) (Fig. 1) there is an obvious relationship: \( z = z' + h \). When \( h \to \infty \):

\[
H^s_z(y, z) = -I_0 N \frac{\zeta}{\gamma} W(y, \Gamma) \left( \frac{\zeta^* e^{-\zeta^* z}}{\zeta^* + \mu_1 \zeta / \mu_0} \right),
\]

\[
H^{(2)}_z(y, z) = -I_0 N \frac{\mu_0}{\gamma} \frac{\zeta}{\gamma} W(y, \Gamma) \left( \frac{\zeta^* e^{-\zeta^* z}}{\zeta^* + \mu_1 \zeta / \mu_0} \right). \quad (40)
\]

where \( x = \gamma R_2 \) is a dimensionless radial transformation parameter; \( \zeta^* = \sqrt{\mu_1^2 \zeta^2 + i \sigma_0 \mu \zeta^2} / \mu_0 \) is a dimensionless complex wave number; \( z' = z'/R_2 \) is a dimensionless axial coordinate; \( \mu_0 \) is a set of dimensionless geometric parameters of the source of alternating magnetic field, that is, the set of values \( R_2 = 1 \); \( R_1 = R_2 / R_2 \); \( \delta = \delta / R_2 \); \( b = b / R_2 \); \( \rho^* = \rho / R_2 \) is a dimensionless radial coordinate. The symbol \( \chi_{\max} = \gamma_{\max} R_2 \) defines the value, which is determined from \( W(y, \Gamma) \).

By the formulas (42) calculations were made with the value of \( \chi_{\max} = 20 \). In this case, the integral was replaced by the algebraic sum of the mean values of the integrands within each section. When performing the calculations, the following formulas were recorded:

\[
R_2 = 3.5 \times 10^{-1} \text{m}; \quad R_1 = 0.5 R_2; \quad b = 0.5 R_2; \quad \delta = 0.1 R_2; \quad I_0 = 60 \text{ A}; \quad N = 10; \quad \mu_1 = \mu_0 = 30 \mu_0; \quad \mu_0 = 4\pi \times 10^{-7} \quad H/\text{m}; \quad r_0 = 15 \text{ mS/m}.
\]

On the surface of a ferromagnet, with small negative values of the axial coordinate \( z' \), the nature of the variation of the real values of the components \( H^s_z(\rho, z') \) and \( H^{(2)}_z(\rho, z') \) in the region \( \rho/R_2 \geq 0 \) can also be explained by the Fig. 3. The dashed curve in Fig. 3 shows the power line of alternating magnetic field. At each moment of time and at any point in the space, the vector \( \vec{H}^s(\rho, z') \) oriented along the tangent to this line.

With further immersion into the depth of the ferromagnetic half-space, the real values of the components \( H^s_z(\rho, z') \) and \( H^{(2)}_z(\rho, z') \) rapidly decrease to zero, after which the sign of the real part of alternating magnetic field is reversed. As the cyclic frequency increases, the plane \( z' = z'_{\max} \) of zero values (the sign inversion plane) of the real value of the intensity vector components of alternating magnetic field begins approaching to the plane \( z' = 0 \). In addition, in the region \( z'_{\max} \leq z' \leq 0 \) with frequency increase, there is an increase in the real values of the radial component \( H^s_z(\rho, z') \) and a decrease in the actual values of the
axial component $H^*_a(\rho, z')$. This can be interpreted as “flattening” or squeezing out the alternating magnetic field of the inductor from the volume of a current-conducting ferromagnet. Obviously, all these effects are due to eddy currents conductivity $J^*_e(\rho, z')$, which generates alternating magnetic field $\bar{H}^*(\rho, z')$ in the volume of a layer of a current-conducting ferromagnet.

From the first equation of the system of Maxwell’s equations (15) it follows that

$$J^*_e(\rho, z') = \text{rot}_e \bar{H}^*(\rho, z'),$$

(43)

where $\text{rot}_e \bar{H}^*(\rho, z')$ is a circumferential component of the vector $\text{rot} \bar{H}^*(\rho, z')$. Substituting the expression (42) into the definition (43), after performing the differentiation operation under the integral sign, we obtain the following expression for calculating the real part of the complex value $J^*_e(\rho, z')$:

$$\text{Re} J^*_e(\rho, z') = \int_0^{2\pi} \text{Re} \left[ \left( \frac{\epsilon' - \mu' \xi^2 / \mu_i}{\epsilon'' + \mu' \xi / \mu_i} \right) e^{i \zeta} \right] W(x, \Gamma) J_0(x) dx.$$

(44)

The analysis of the calculations results using formula (44) allows to conclude that the plane coordinate $\zeta_0$ of zero values of the real part of the complex density of the eddy current of conductivity does not coincide with the plane coordinate $z'_0$ of the inversion of the sign of the real values of the components of the intensity vector of alternating magnetic field.

Ponderomotive effect of electromagnetic field over a metallic sample is defined by surface densities of Maxwell forces $\sigma_{\text{sn}}(\rho, t) = B_2^0 H^*_a(\rho, 0) e^{i\omega t}$ and $\sigma_{\text{sn}}^M(\rho, t) = 0.5 B_2^0 H^*_a(\rho, 0) e^{i\omega t}$, where $H^*_a(\rho, 0)$ ($\beta = \rho, z$) are amplitude values of the components of the intensity vector of alternating magnetic field in the volume of the metal, determined on the surface $z' = 0$ of a metallic half-space.

The amplitude values of the components of the vector of the volume density of Lorentz forces are determined by the following expressions $f^*_{\text{sn}}(\rho, z') = B_2^0 J^*_e(\rho, z')$, $f^*_{\text{sn}}(\rho, z') = 0$, where $J^*_e(\rho, z')$ is an amplitude value of the surface density of the eddy current conductivity.

In a ferromagnetic metal, in addition to the deformations that are created by the ponderomotive action of the electromagnetic field, deformations appear due to the direct magnetostrictive effect or Joule effect. These deformations can be associated with Joule forces or magnetostrictive forces that are on the surface and in the volume of a ferromagnet. The surface density of Joule forces is determined by the following expressions:

$$\sigma_{\text{sn}}(\rho, t) = \frac{m_1 - m_2}{2 \mu_0} B_2^0 H^*_a(\rho, 0) e^{i\omega t},$$

$$\sigma_{\text{sn}}^M(\rho, t) = \frac{m_1}{\mu_0} B_2^0 H^*_a(\rho, 0) e^{i\omega t}.$$

(45)

If $B_2^0 / \mu_0 \equiv H^*_a$, where $H^*_a$ approximately corresponds to the magnetic field at the middle of the region of irreversible displacements of the domain walls on the initial magnetization curve [2], then the following estimate of the magnetostrictive constants is made: $m_1 \leq 0.1 H/m$, $m_2 \equiv m_1/2$.

In the volume of a ferromagnet, the Joule forces are characterized by a volume density vector $f^*_{\text{sn}}(\rho, z') e^{i\omega t}$, for which the amplitude values of components are determined by the following expressions:

$$f^*_{\text{sn}}(\rho, z') = \frac{\partial \sigma_{\text{sn}}(\rho, z')}{\partial \rho} + \frac{1}{\rho} \left[ \sigma_{\text{sn}}(\rho, 0) - \sigma_{\text{sn}}(\rho, z') \right],$$

(46)

$$f^*_{\text{sn}}(\rho, z') = \frac{\partial \sigma_{\text{sn}}(\rho, z')}{\partial \rho} + \frac{1}{\rho} \sigma_{\text{sn}}(\rho, 0) + \frac{\partial \sigma_{\text{sn}}(\rho, z')}{\partial z}.$$  

(47)

Amplitude values of the surface densities $\sigma_{\text{sn}}(\rho, z')$ and $\sigma_{\text{sn}}^M(\rho, z')$ are defined as follows: $\sigma_{\text{sn}}(\rho, z') = \sigma_{\text{sn}}(\rho, 0)$, $\sigma_{\text{sn}}^M(\rho, z') = (m_2 / \mu_0) B_2^0 H^*_a(\rho, 0)$.

After determining the Hankel integral images of the amplitude values of the intensity vector components of alternating magnetic field and the eddy current conductivity in the volume of a ferromagnet, we can write the relations for calculating the integral images of the
force factors that are in the skin layer and in the volume of magnetized, anisotropic based on magnetic properties metal, and which are sources of ultrasonic waves

a) ponderomotive forces of the electromagnetic field

\[ \sigma_M^m(y,0) = \frac{I_0N B_0^0}{\gamma} \left( \frac{\mu_0^\gamma / |\mu_0^\gamma|}{\zeta + \mu_0^\gamma / |\mu_0^\gamma|} \right)^2 W(y,\gamma); \]  
\[ f^m_\rho(y,0) = \frac{I_0N B_0^0}{\gamma} \left( \frac{i\sigma_0^m \mu_0^\gamma / |\mu_0^\gamma|}{\zeta + \mu_0^\gamma / |\mu_0^\gamma|} \right)^2 W(y,\gamma) e^{i\phi}; \]  
\[ f^m_z(y,0) = 0; \]  

b) surface and volume Joule forces:

\[ \sigma_M^p(y) = \frac{1}{2\mu_0^p} \left( \frac{m_1 - m_2}{m_1 + \mu_0^p} \right)^2 \frac{I_0N B_0^0}{\gamma} \left( \frac{\mu_0^\gamma / |\mu_0^\gamma|}{\zeta + \mu_0^\gamma / |\mu_0^\gamma|} \right)^2 W(y,\gamma); \]  
\[ f^p_\rho(y,0) = \frac{1}{2\mu_0^p} \left( \frac{m_1 - m_2}{m_1 + \mu_0^p} \right)^2 \frac{I_0N B_0^0}{\gamma} \left( \frac{\mu_0^\gamma / |\mu_0^\gamma|}{\zeta + \mu_0^\gamma / |\mu_0^\gamma|} \right)^2 W(y,\gamma) e^{i\phi}; \]  
\[ f^p_z(y,0) = \left[ \frac{1}{2\mu_0^p} \left( \frac{m_1 - m_2}{m_1 + \mu_0^p} \right)^2 \frac{I_0N B_0^0}{\gamma} \left( \frac{\mu_0^\gamma / |\mu_0^\gamma|}{\zeta + \mu_0^\gamma / |\mu_0^\gamma|} \right)^2 \right] W(y,\gamma) e^{i\phi}. \]

Expressions (51) and (52) are written under the assumption that \(|\zeta| > \gamma\). Indeed, with moderate specific electrical conductivity \(r_0 \leq 10\) mS/m and magnetic permeability \(\mu_0^P \approx \mu_0^P = 30\mu_0 = 3.77 \times 10^{-5}\) m the product is \(\sigma_0^m \mu_0^P = 2.37 \times 10^7 / \mu_0^P\), where \(\mu_0^P\) is the value of the cyclic frequency in megahertz, in this case \(\gamma^2 < \gamma^2_{\text{max}} = 1.6 \times 10^7\).

The ratio \(\gamma^2 / (i\sigma_0^m \mu_0^P) \leq 6.75 \times 10^{-3} / \mu_0^P\) decreases with increasing frequency and becomes significantly less than unity, starting at a frequency of 100 kilohertz. For this reason \(\zeta^2 = \gamma^2 + i\sigma_0^m \mu_0^P \approx i\sigma_0^m \mu_0^P\) and \(\zeta^2 = i\sigma_0^m \mu_0^P\), provided that \(|\zeta| > \gamma\).

It follows from the calculated formulas (48) - (52) that

\[ \frac{\sigma_M^m(y)}{\sigma_M^p(y)} = 2\mu_0^p, \quad \frac{\sigma_M^p(y)}{\sigma_M^p(y)} = \frac{\mu_0^P}{m_1} \quad \text{for} \quad 0 < \gamma < 100. \]

If the magnetostrictive constants \(m_1\) and \(m_2\) are not less than \(0 \leq H / m\), then \(\mu_0^P = 30\mu_0 = 3.77 \times 10^{-5}\) H/m, the ratio of the surface densities of the ponderomotive forces of the electromagnetic field and the Joule forces, determined by expressions (53), take the following values \(\sigma_M^m(y) / \sigma_M^p(y) = 5.03 \times 10^{-4}\) and

\[ \sigma_M^m(y) / \sigma_M^p(y) = 3.77 \times 10^{-4}. \]

Since the ratio of bulk densities is \(f^m_\rho(y) / f^p_\rho(y) = 2\mu_0^P / (m_1 - m_2) = 5.03 \times 10^{-4}\), it can be concluded that with a correctly selected magnetization field of the ferromagnet, the Joule forces, namely the direct magnetostrictive effect, is the dominant mechanism for the formation of deformations in the electromagnetic method of excitation of ultrasonic waves in ferromagnetic metals. Naturally, there are no magnetostrictive effects in the non-ferromagnetic metals and the only mechanism for excitation of ultrasonic waves is the ponderomotive force of the electromagnetic field.

Obviously, the surface densities of Joule forces \(\sigma_M^p(\rho)\) and \(\sigma_M^p(\rho)\) in the given model situation depend on the radial variable \(\rho\) in the same way as the components \(H^i_\rho(\rho,0)\) and \(H^i_\rho(\rho,0)\). In other words, they change on the surface \(z = 0\) in the same way as the dependences under the numbers 1 in Fig. 4 and Fig. 5. From this obvious fact it follows that at frequencies when the sign of alternating magnetic field is reversed \(f > 100\) kHz and \(\rho > 0\) a strong inequality is satisfied

\[ |\sigma_M^p(\rho)| > |\sigma_M^p(\rho)|. \]

The real parts of the volume density vector components of Joule forces are determined by the following expressions

\[ \text{Re} f^m_\rho(\rho,0) \equiv \frac{I_0N B_0^0}{2\mu_0^P R_1^2} (m_1 - m_2) \frac{e^{i\gamma x \rho}}{\zeta + \mu_0^P x / \mu_0} W(x,\gamma) j_0(x \rho) dx, \]

\[ \text{Re} f^m_z(\rho,0) \equiv \frac{I_0N B_0^0}{2\mu_0^P R_1^2} \left[ m_1 (1 - 2\mu_0^P x / m_1) - m_2 \right] \frac{e^{i\gamma x \rho}}{\zeta + \mu_0^P x / \mu_0} W(x,\gamma) j_0(x \rho) dx. \]

The formula (54) allowed to calculate and investigate the changes in radial and axial volumetric Joule force density vector components for the case of altering magnetic field, which changes with frequencies of 100 kHz and 1 MHz. The value of the magnetic induc-
Физические основы создания бесконтактных ультразвуковых частотных сенсоров для исследования нанокристаллических ферромагнитных материалов

Розроблена математична модель по определению силовых воздействий, формируемых при преобразовании электромагнитного поля в поле ультразвуковых колебаний в скин-слой электропроводного ферромагнитного материала анизотропного по магнитной проницаемости. Установлены основные факторы, определяющие возбуждаемое акустическое поле с учетом допустимых ограничений. Показано, что основной вклад в энергию ультразвуковых колебаний вносит магнитострикционная составляющая материала скин-слой, в котором происходит преобразование высокочастотного электromагнитного поля в акустическое.

Ключевые слова: Математическая модель, Преобразование полей, Границная задача, Скин-слой металла, Ферромагнетик, Электропроводный материал, Упругие колебания, Электромагнитное поле, Силовое воздействие.
Фізичні основи створення безконтактних ультразвукових частотних сенсорів для дослідження нанокристалічних феромагнітних матеріалів

Розроблено математичну модель по визначенню силових впливів, які формуються при перетворенні електромагнітного поля в поле ультразвукових коливань в скін-шарі електропровідного феромагнітного матеріалу анізотропного по магнітній проникності. Встановлено основні фактори, що визначають збуджене акустичне поле з урахуванням допустимих обмежень. Показано, що основний внесок в енергетику акустичних коливань вносять магнітострикційна складова матеріалу скін-шару, в якому відбувається перетворення високочастотного електромагнітного поля в акустичне.

Ключові слова: Математична модель, Перетворення полів, Гранічна задача, Скін-шар металу, Феромагнетик, Електропровідний матеріал, Пружні коливання, Електромагнітне поле, Силовий вплив.
